Abstract

The traditional process of searching for renters and managing rental properties for landlords within the local Paniqui municipality is often restricted by inconsistent information, outdated advertisements, and a lack of transparency. This study focuses the development and evaluation of “Apartrent: Apartment Management System” a localized web-based rental system specifically designed to centralize housing listings and effectively modernizing and simplifying the connection between landlords and tenants. The system features a searchable verified listings, integrated GPS mapping for precise location tracking, and 360-degree panoramic views that allow the interested renters for virtual property inspections mitigating the need of physical inspections. Using a quantitative research design, the system’s acceptability was measured through a survey involving local resident respondents, focusing on usability, design, navigation, information, and user-friendliness.

The results of the evaluation indicated a high level of acceptance, with a significant majority of the included respondents such as renters and landlords, strongly agreeing that the system is intuitive, aesthetically pleasing, and highly functional. The findings conclude that “Apartrent: Apartment Management System” effectively modernizes the local rental market, providing a reliable, efficient, and transparent digital solution that addresses the municipality’s growing housing needs.
